a) How to capture the date ?

When double-click a date on calendar, can open which the date's Event Dialog, so How to capture the date ? that means is: how to know which date was be click ?

b) Is it possible to capture the tooltip's strings ?

For example: when mouse is over the event-date on calendar, it will popup the tooltip display the all events of the date. so i'm thinking to know, is there any way can capture the tooltip's strings? because if is can be, then i can do the similar working - "viewing tasks/events by date". that means is: if i click a date on calendar, i can display the all events of the date at other place (e.g. a new text-window).

a) You could try adding a mouse click handler and calculate the day that was clicked but that can get quite tricky. I can see if it would be possible to add a special handler event for this.

b) That's not possible. I think I need to create a new function to get the events/tasks for a given day. I'll add this to my backlog.

Rainy, you already made the Rainlendar\_ListAllComponents() function to get the events for a given day, which return a table of UIDs to use with Rainlendar\_GetComponent() (extracted from help)

The problem with ListAllComponents is: "If the date parameter is given only the events (not tasks!) on that day are returned."

I had already forgotten that you could give the date as parameter for that function. I can change it to return tasks too.
