
Can Rainlendar run in a widget layer?

Posted by Icarus3000 - 2007/03/05 08:50

I am running Rainlendar 2.02 Pro under Linux (Ubuntu 6.10 with Beryl).

Beryl has an option to run applications in a widget layer, which can be forced by entering the "wmname" from "xwininfo".

Unfortunately, when I select the rainlendar windows from xwininfo, it apparently has no name.

Is there any way to do this? If not currently, would it be difficult in future versions to give Rainlendar a wmName?

Thanks!

I'll check if I can add names to the windows.

this would be really useful, under winOS one could use AutoHotKey to map keystrokes and mouse buttons to rl functions etc. and Dexpot virtual desktop manager also could be configured to customize rl in a window. but both require a window name.
