## Global variables

---

Can you please add global variables that can be accessed from all windows? For example, I want to use variables to set the color of my skin, but I need one for each window. It would be better if I could have a global variable for color that applied to all the windows.

The manual says this:

window - Defines the window where the variable is defined. If the same variable is used in several windows you need to create a separate element for each window. If this attribute is not defined the variable is set in all windows (and it will also show in the settings dialog for every window)

Have you tried it like that? Does it work?

It does not work.

The variables does indeed appear in the Settings dialog for all the windows, but I cannot access it from the other windows in the XML file.
