
2* TCPIIn/TCPOut?

Posted by ChopstickNINJ4 - 2009/02/26 01:44

For some reason I am getting double the actual bandwidth for the TCPIIn/out values. Someone please help me :(I've scoured forums already and I can't find the answer.

On a side note I have 2 Ethernet ports on my computer, I tried using Interface=1, but that just causes the plugin to crap out and display 0 all the time. Even Interface=0 which is supposed to add all the NICS together still gets stuck at 0...

One possibility might be that your loopback interface isn't called "MS TCP Loopback interface" so it gets added to the total amount. Try with other Interface values and see if you can find the interface which connected to the network.

I've tried interface values from 0-10 and it still gets stuck displaying 0. Is there anything else I can do?

You could try to get the network usage from the performance counters with the PerfMon plugin if the build-in functionality doesn't work properly.

Er... rainmeter crapped out my system... Everything that rainmeter has a plug-in for i can't get the snap-in to load in performance monitor.

Wow... almost ALL my perfmon snap-ins don't load

The exact wording of the error is: "MMC cannot initialize the snap-in" which I get when I click on "Performance Monitor" under "Reliability and Performance Monitor"

So, are you saying that you get the error only if Rainmeter is running when you open the management console? That's weird. I wouldn't have thought that reading the performance counters has such side-effect. What version of Windows do you have?

Hmm no I think it was window's update I can't get the performance counters back. I'm running Server 2008 that I've tried converting to a workstation following win2008workstation.com I'm trying to find a way to rebuild the counters right now. The worst part is there's incredibly little documentation on Server 2008 :-)
